

# Object-Oriented Software Engineering

Using UML, Patterns, and Java

## Chapter 10, Mapping Models to Code

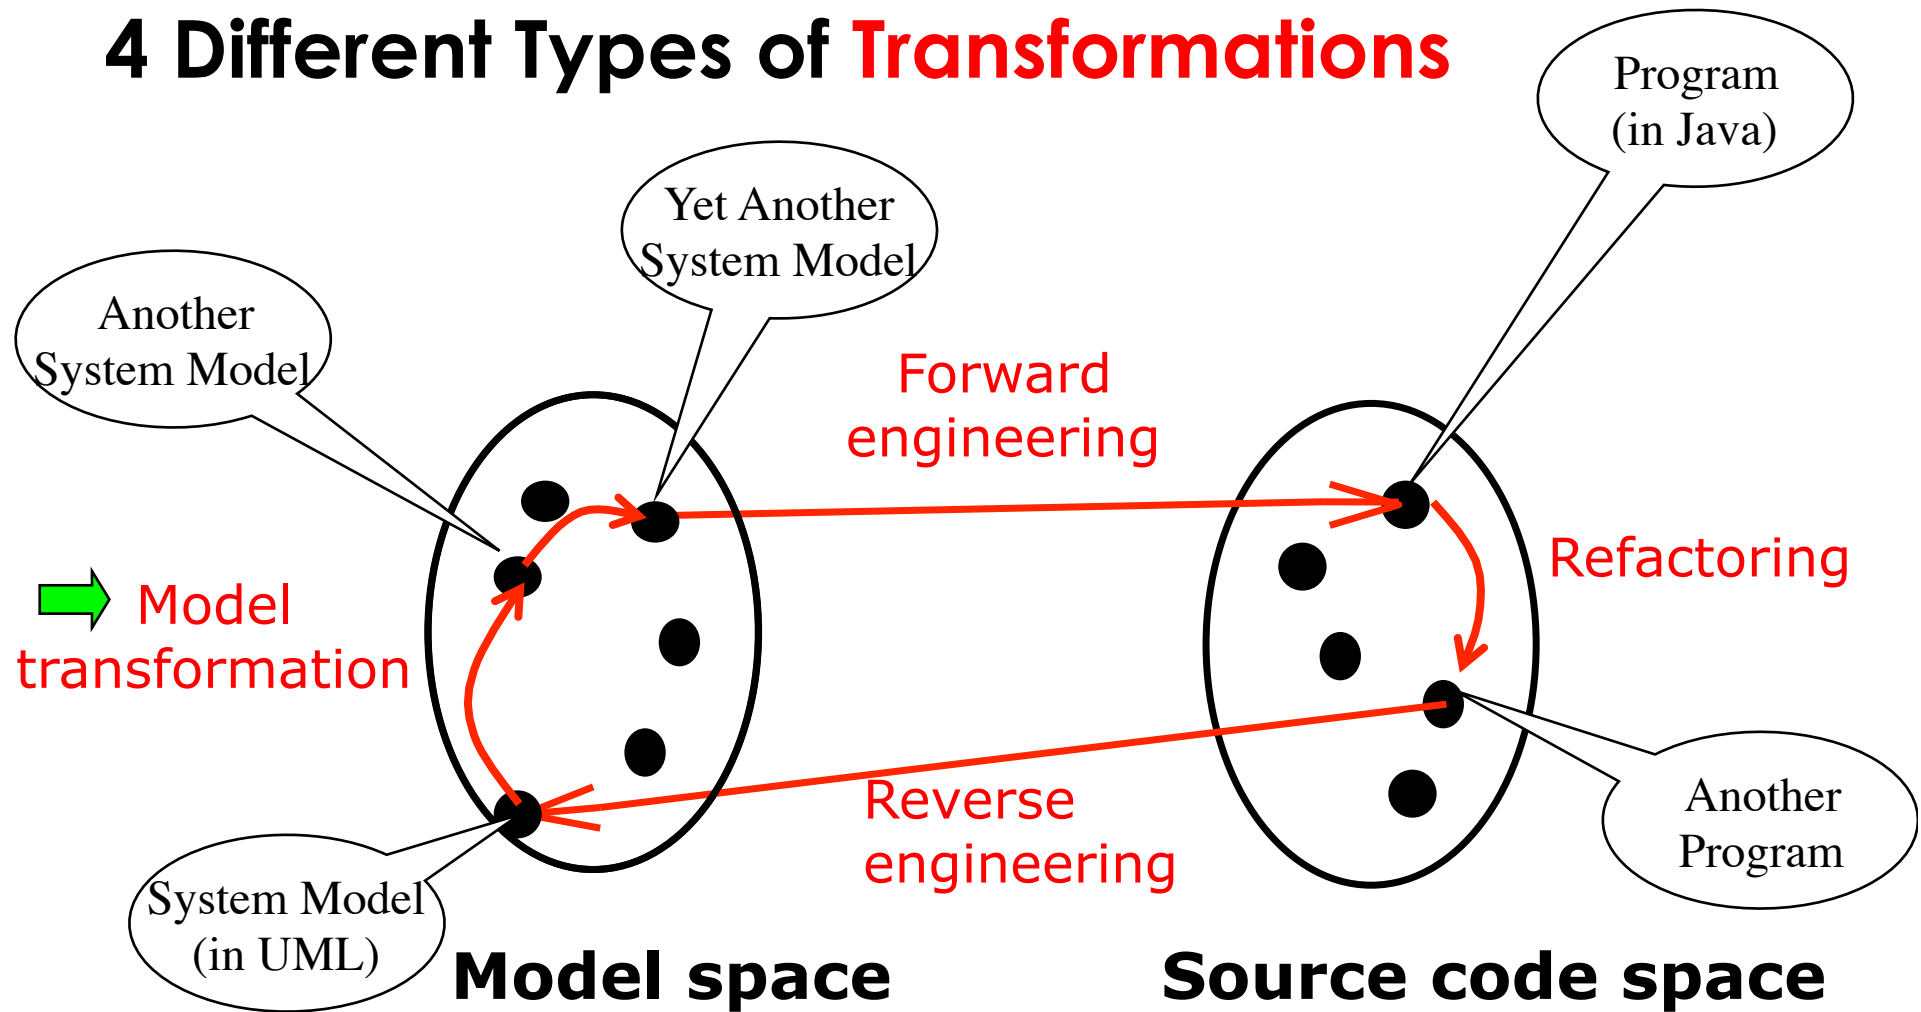

# Lecture Plan

- Part 1
  - Operations on the object model:
    - Optimizations to address performance requirements
  - Implementation of class model components:
    - Realization of associations
    - Realization of operation contracts
- Part 2
  - Realizing entity objects based on selected storage strategy
  - Mapping the object model to a storage schema
  - Mapping class diagrams to tables

# Problems with implementing an Object Design Model

- **Programming languages do not support** the concept of **UML associations**
  - The associations of the object model must be transformed into collections of object references
- **Many programming languages do not support contracts** (invariants, pre and post conditions)
  - Developers must therefore manually transform contract specification into source code for detecting and handling contract violations
- The **client changes the requirements** during object design
  - The developer must change the contracts in which the classes are involved
- All these object design activities cause **problems**, because they need to be done manually.

# 4 Different Types of Transformations

# Model Transformation

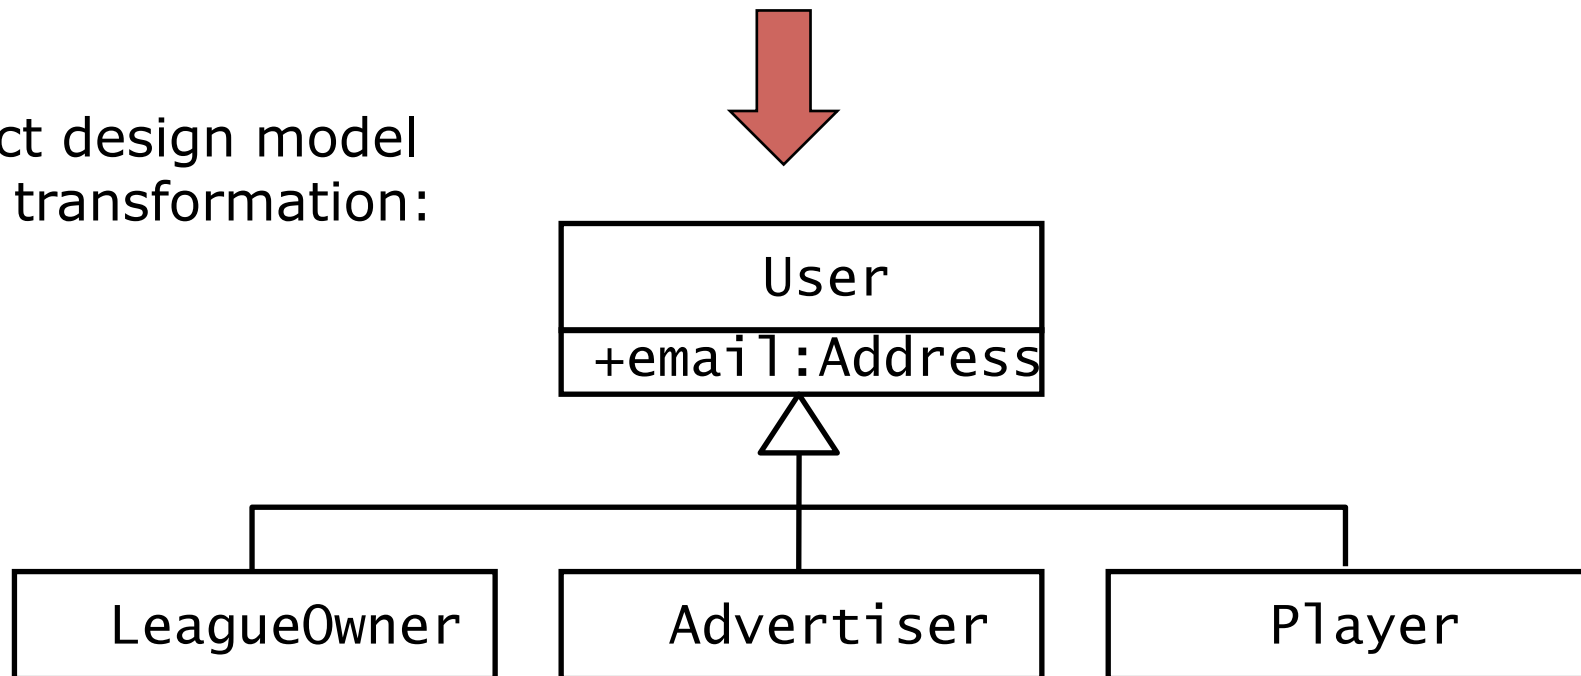

- Takes as input a model conforming to a meta model (for example the MOF metamodel) and produces as output another model conforming to the metamodel
- Model transformations are used in MDA (Model Driven Architecture).

# Model Transformation Example

Object design model before transformation:

Object design model after transformation:

# Refactoring : Pull Up Field

```
public class Player {  
    private String email;  
    //...  
}  
  
public class LeagueOwner {  
    private String eMail;  
    //...  
}  
  
public class Advertiser {  
    private String  
    email_address;  
    //...  
}
```

```
public class User {  
    private String email;  
}  
  
public class Player extends User {  
    //...  
}  
  
public class LeagueOwner extends  
    User {  
    //...  
}  
  
public class Advertiser extends  
    User {  
    //...  
}.
```

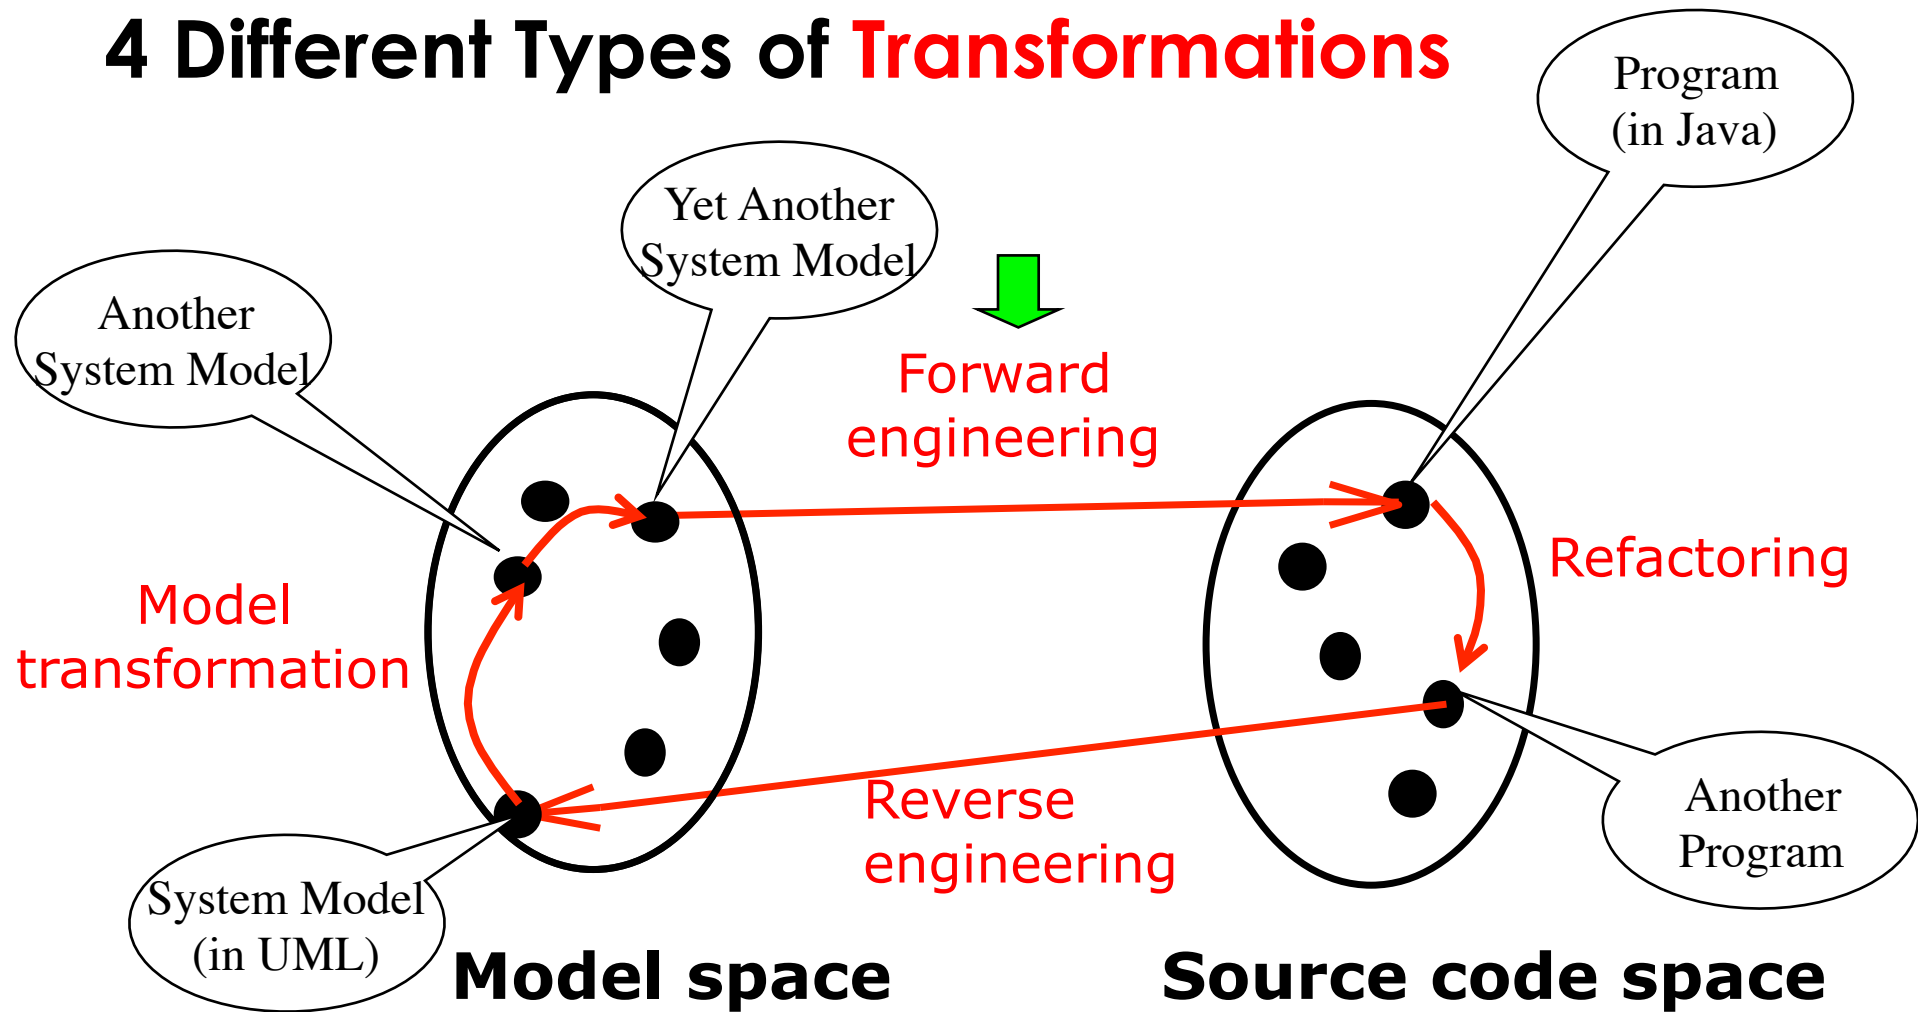

# Refactoring Example: Pull Up Constructor Body

```
public class User {  
    private String email;  
}  
  
public class Player extends User {  
    public Player(String email) {  
        this.email = email;  
    }  
}  
  
public class LeagueOwner extends  
    User {  
    public LeagueOwner(String email)  
    {  
        this.email = email;  
    }  
}  
  
public class Advertiser extends  
    User {  
    public Advertiser(String email) {  
        this.email = email;  
    }  
}
```

```
public class User {  
    public User(String email) {  
        this.email = email;  
    }  
}  
  
public class Player extends User {  
    public Player(String email) {  
        super(email);  
    }  
}  
  
public class LeagueOwner extends  
    User {  
    public LeagueOwner(String email) {  
        super(email);  
    }  
}  
  
public class Advertiser extends  
    User {  
    public Advertiser(String email) {  
        super(email);  
    }  
}
```

# 4 Different Types of Transformations

# Forward Engineering Example

Object design model before transformation:

Source code after transformation:

```
public class User {
    private String email;
    public String getEmail() {
        return email;
    }
    public void setEmail(String e){
        email = e;
    }
    public void notify(String msg) {
        // ....
    }
}
```

```
public class LeagueOwner extends User {
    private int maxNumLeagues;
    public int getMaxNumLeagues() {
        return maxNumLeagues;
    }
    public void setMaxNumLeagues(int n) {
        maxNumLeagues = n;
    }
}
```

# More Forward Engineering Examples

- Model Transformations
  - Goal: Optimizing the object design model
    - ➡ Collapsing objects
- Forward Engineering
  - Goal: Implementing the object design model in a programming language
  - Mapping inheritance
  - Mapping associations
  - Mapping contracts to exceptions
  - Mapping object models to tables

# Collapsing Objects

Object design model before transformation:

Object design model after transformation:

Turning an object into an attribute of another object is usually done, if the object does not have any interesting dynamic behavior (only get and set operations).

# Examples of Model Transformations and Forward Engineering

- Model Transformations
  - Goal: Optimizing the object design model
    - Collapsing objects
    - Delaying expensive computations
- Forward Engineering
  - Goal: Implementing the object design model in a programming language
  - ➡ Mapping inheritance
    - Mapping associations
    - Mapping contracts to exceptions
    - Mapping object models to tables

# Forward Engineering: Mapping a UML Model into Source Code

- **Goal:** We have a UML-Model with inheritance. We want to translate it into source code
- **Question:** Which mechanisms in the programming language can be used?
  - Let's focus on Java
- Java provides the following mechanisms:
  - Overwriting of methods (default in Java)
  - Final classes
  - Final methods
  - Abstract methods
  - Abstract classes
  - Interfaces.

# Realizing Inheritance in Java

- Realisation of specialization and generalization
  - Definition of subclasses
  - Java keyword: **extends**
- Realisation of strict inheritance
  - Overwriting of methods is not allowed
  - Java keyword: **final**
- Realisation of implementation inheritance
  - Overwriting of methods
  - No keyword necessary:
    - Overwriting of methods is default in Java
- Realisation of specification inheritance
  - Specification of an interface
  - Java keywords: **abstract, interface.**

# Examples of Model Transformations and Forward Engineering

- Model Transformations
  - Goal: Optimizing the object design model
    - ✓ Collapsing objects
- Forward Engineering
  - Goal: Implementing the object design model in a programming language
    - ✓ Mapping inheritance
  - ➡ Mapping associations
    - Mapping contracts to exceptions
    - Mapping object models to tables

# Mapping Associations

1. Unidirectional one-to-one association
2. Bidirectional one-to-one association
3. Bidirectional one-to-many association
4. Bidirectional many-to-many association
5. Bidirectional qualified association.

# Unidirectional one-to-one association

Object design model before transformation:

Source code after transformation:

```
public class Advertiser {
    private Account account;
    public Advertiser() {
        account = new Account();
    }
}
```

Red arrows point from the 'Advertiser' box in the UML diagram to the 'Advertiser' class definition, and from the 'Account' box to the 'private Account account;' line in the code.

# Bidirectional one-to-one association

Object design model before transformation:

Source code after transformation:

```
public class Advertiser {
/* account is initialized
 * in the constructor and never
 * modified. */
private Account account;
public Advertiser() {
    account = new Account(this);
}
public Account getAccount() {
    return account;
}
}
```

```
public class Account {
/* owner is initialized
 * in the constructor and
 * never modified. */
private Advertiser owner;
public Account(owner:Advertiser) {
    this.owner = owner;
}
public Advertiser getOwner() {
    return owner;
}
}
```

# Bidirectional one-to-many association

Object design model before transformation:

Source code after transformation:

```
public class Advertiser {
    private Set accounts;
    public Advertiser() {
        accounts = new HashSet();
    }
    public void addAccount(Account a) {
        accounts.add(a);
        a.setOwner(this);
    }
    public void removeAccount(Account a) {
        accounts.remove(a);
        a.setOwner(null);
    }
}
```

```
public class Account {
    private Advertiser owner;
    public void setOwner(Advertiser
newOwner) {
    if (owner != newOwner) {
        Advertiser old = owner;
        owner = newOwner;
        if (newOwner != null)
            newOwner.addAccount(this);
        if (oldOwner != null)
            old.removeAccount(this);
    }
}
```

# Bidirectional many-to-many association

Object design model before transformation

Source code after transformation

```
public class Tournament {
    private List players;
    public Tournament() {
        players = new ArrayList();
    }
    public void addPlayer(Player p) {
        if (!players.contains(p)) {
            players.add(p);
            p.addTournament(this);
        }
    }
}
```

```
public class Player {
    private List tournaments;
    public Player() {
        tournaments = new ArrayList();
    }
    public void addTournament(Tournament t) {
        if (!tournaments.contains(t)) {
            tournaments.add(t);
            t.addPlayer(this);
        }
    }
}
```

# Examples of Model Transformations and Forward Engineering

- Model Transformations
  - Goal: Optimizing the object design model
    - ✓ Collapsing objects
    - ✓ Delaying expensive computations
- Forward Engineering
  - Goal: Implementing the object design model in a programming language
    - ✓ Mapping inheritance
    - ✓ Mapping associations
  - Next! ➡ Mapping contracts to exceptions
  - Mapping object models to tables

# Implementing Contract Violations

- Many object-oriented languages do not have built-in support for contracts
- However, if they support exceptions, we can use their exception mechanisms for signaling and handling contract violations
- In Java we use the try-throw-catch mechanism
- Example:
  - Let us assume the `acceptPlayer()` operation of `TournamentControl` is invoked with a player who is already part of the `Tournament`
    - UML model
  - In this case `acceptPlayer()` in `TournamentControl` should throw an exception of type `KnownPlayer`
    - Java Source code.

# The Try-throw-catch mechanism

- The first step in constructing an exception handler is to enclose the code that might throw an exception within a try block. In general, a try block looks like the following:

```
try {  
    code  
}
```

```
catch (ExceptionType name) {  
...  
}  
catch (ExceptionType name) {  
...  
}
```

*From:  
Catching and Handling  
Exceptions  
<http://docs.oracle.com/javase/tutorial/essential/exceptions/handling.html>*

# The Try-throw-catch mechanism/2

- Each catch block is an exception handler and handles the type of exception indicated by its argument.
  - The argument type, `ExceptionType`, declares the type of exception that the handler can handle and must be the name of a class that inherits from the **Throwable** class. The handler can refer to the exception with name.

```
try {  
    code  
}
```

```
catch (ExceptionType name) {  
    ...  
}
```

```
catch (ExceptionType name) {  
    ...  
}
```

# The Try-throw-catch mechanism/3

- The catch block contains code that is executed if and when the exception handler is invoked.

```
try {  
    code  
}
```

```
catch (ExceptionType name) {  
    ...  
}
```

```
catch (ExceptionType name) {  
    ...  
}
```

# The Try-throw-catch mechanism/4

- The following are examples of exception handlers
- The first handler, in addition to printing a message, throws a user-defined exception: `SampleException(e)`.

```
try {  
    code  
  
} catch (FileNotFoundException e) {  
    System.err.println("FileNotFoundException: " +  
                        e.getMessage());  
    throw new SampleException(e);  
  
} catch (IOException e) {  
    System.err.println("Caught IOException: " +  
                        e.getMessage());  
}
```

# The Try-throw-catch mechanism/5

- The **finally** block always executes when the try block exits. This ensures that the finally block is executed even if an unexpected exception occurs.

```
try {  
    } catch (FileNotFoundException e) {  
        System.err.println("FileNotFoundException: " +  
                           e.getMessage());  
        throw new SampleException(e);  
    } catch (IOException e) {  
        System.err.println("Caught IOException: " +  
                           e.getMessage());  
    }  
finally {  
    if (out != null) {  
        System.out.println("Closing PrintWriter");  
        out.close();  
    } else {  
        System.out.println("PrintWriter not open");  
    }  
}
```

# Implementing a Contract

- **Check each precondition:**
  - Before the beginning of the method with a test to check the precondition for that method
    - Raise an exception if the precondition evaluates to false
- **Check each postcondition:**
  - At the end of the method write a test to check the postcondition
    - Raise an exception if the postcondition evaluates to false. If more than one postcondition is not satisfied, raise an exception only for the first violation.
- **Check each invariant:**
  - Check invariants at the same time when checking preconditions and when checking postconditions
- **Deal with inheritance:**
  - Add the checking code for preconditions and postconditions also into methods that can be called from the subclass.

# Summary

- Strategy for implementing associations:
  - Be as uniform as possible
  - Individual decision for each association
- Example of uniform implementation
  - 1-to-1 association:
    - Role names are treated like attributes in the classes and translate to references
  - 1-to-many association:
    - "Ordered many" : Translate to Vector
    - "Unordered many" : Translate to Set
  - Qualified association:
    - Translate to Hash table
